**ABSTRACT:** At present, there is a considerable increase in the amount of data stored in storage services, along with dramatic evolution of networking techniques. In storage services with huge data, the storage servers may want to reduce the volume of stored data, and the clients may want to monitor the integrity of their data with a low cost, since the cost of the functions related to data storage increase in proportion to the size of the data. To achieve these goals, secure deduplication and integrity auditing delegation techniques have been studied, which can reduce the volume of data stored in storage by eliminating duplicated copies and permit clients to efficiently verify the integrity of stored files by delegating costly operations to a trusted party, respectively. So far many studies have been conducted on each topic, separately, whereas relatively few combined schemes, which support the two functions simultaneously, have been researched. In this paper, we design a combined technique, which performs both secure deduplication of encrypted data and public integrity auditing of data. To support the two functions, the proposed scheme performs challenge-response protocols using the BLS signature-based homomorphic linear authenticator. We utilize a third party auditor for performing public audit, in order to help low-powered clients. The proposed scheme satisfies all the fundamental security requirements. We also propose two variances that provide higher security and better performance.

KEYWORDS: Cloud storage, cryptography, data security, information security, public audit, secure deduplication.

### I. INTRODUCTION

In cloud storage services, clients outsource data to a remote storage and access the data whenever they need the data. Recently, owing to its convenience, cloud storage services have become widespread, and there is an increase in the use of cloud storage services. Well-known cloud services such as Dropbox and iCloud are used by individuals and businesses for various applications. A notable change in information- based services that has happened recently is the volume of data used in such services due to the dramatic evolution of network techniques. For example, in 5G networks, gigabits of data can be transmitted per second, which means that the size of data that is dealt by cloud storage services will increase due to the performance of the new networking technique. In this viewpoint, we can characterize the volume of data as a main feature of cloud storage services. Many service providers have already prepared high resolution contents for their service to utilize faster networks. For secure cloud ser- vices in the new era, it is important to prepare suitable security tools to support this change. Larger volumes of data require higher cost for managing the various aspects of data, since the size of data to be stored. In this viewpoint, it is desirable for storage servers to reduce the volume of data, since they can increase their profit by reducing the cost for maintaining storage data stored in the storage maintained by service providers.

In this viewpoint, clients may want to verify the integrity with a low cost regardless of the size of data. Owing to the demands of storage servers and clients, many researches on this topic are available in the literature.

### Vol. 7, Issue 7, July 2019

To reduce the volume of data, deduplication has to be performed in servers so that the storage space efficiency can be improved by removing duplicated copies. According to the research report of EMC, about 75% of the data are duplicated [7]. This fact raises the need for design of deduplication technology. In the literature, there are studies on two types of deduplication techniques. Among them, client-side dedu- plication has attracted the interest of researchers more than server-side deduplication due to its efficiency in computation and communication. Unfortunately, client-side deduplication has a number of problems. In [9], Harnik et al. discovered some attack scenarios related to client-side deduplication, which can lead to data leakage in the worst case. So far, many schemes and techniques have been introduced to sup- port secure deduplication. In [8], Halevi et al. introduced the concept of proofs of ownership (PoW). Keelveedhi et al. [11] formalized a class of message-locked encryptions including an existing convergent encryption (CE), and presented a new deduplication technique called DupLESS which is the first deduplication mechanism that can ensure semantic security.

When clients use cloud storage services, the integrity of stored data is the most important requirement. In other words, clients want to be guaranteed about the integrity of their data in the cloud. In cloud storage services, we cannot exclude the possibility of weak cloud servers, which are vulnerable to internal and external security threats. In the case of data loss due to some incident, weak servers may try to hide the fact that they lost some data, which were entrusted by their clients. More seriously, servers delete rarely accessed users' data in order to increase the profit. Therefore, it is a natural requirement of clients to periodically check the current state of their data. To do this in practice, we need a way to efficiently check the integrity of data in remote stor- age. So far, various schemes have been proposed including proof of retrievability (POR) schemes [4], [10], [14], [17] and provable data possession (PDP) schemes [1], [2], [6], [15]. Secure deduplication and integrity auditing are fundamental functions required in cloud storage services. Hence, individual researches have been actively conducted on these two topics. However, relatively few studies have been conducted for designing a combined scheme that can support these two functions at the same time. The fundamental goal of the design of a combined model is to guarantee less overhead than a trivial combination of existing schemes. In particular, the goal of this paper is to improve the cost of both computa- tion and communication.

In this paper, we design a new scheme for secure and efficient cloud storage service. The scheme supports both secure deduplication and integrity auditing in a cloud environment. In particular, the proposed scheme provides secure deduplication of encrypted data. Our scheme performs PoW for secure deduplication and integrity auditing based on the homomorphic linear authenticator (HLA), which is designed using BLS signature. The proposed scheme also supports public auditing using a TPA (Third Party Auditor) to help low-powered clients. The proposed scheme satisfies all fundamental security requirements, and is more efficient than the existing schemes that are designed to support deduplica- tion and public auditing at the same time. Note that the pre- liminary version of this paper appeared in MobiSec2017 [16]. The main improvement in this paper is that we propose two variations to provide higher security and better performance. In the first variance, which is designed for stronger security, we assume a stronger adversary and provide a counter mea- sure against the adversary. In the second variance, we design a technique that supports a very low-powered client and entrusts more computation to the cloud storage server in the upload procedure.

This paper is organized as follows. Section II describes related works. In Section III, we propose a secure deduplication technique, which supports integrity auditing based on BLS signature, and analyze it in Section IV. In addition, we suggest two improved protocols in Section V. Finally, Section VI provides the conclusion.

### II. RELATED WORKS

Secure deduplication is interesting for both industrial and research communities; therefore, several secure deduplication schemes have been proposed. Harnik et al. [9] showed some attacks in the case of client-side deduplication, which causes data leakage. To counter the attacks, the concept of PoW was introduced in [8]. Later, in [11], the convergent encryption, which is defined as message-locked encryption, was formalized and then, Bellare et al. presented another scheme called DupLESS for semantic security.

To support data integrity, two concepts, PDP and POR, have been introduced. Ateniese et al. [1] introduced PDP for ensuring that the cloud storage providers actually possess the files without retrieving or downloading the entire data. It is

### Vol. 7, Issue 7, July 2019

basically a challenge-response protocol between the verifier (a client or TPA) and the prover (a cloud). Compared to PDP, POR not only ensures that the cloud servers possess the target files, but also guarantees their full recovery [10]. Since then, a number of POR schemes [4], [14], [17] and PDP schemes [2], [6], [15] have been proposed.

A simple combination of two independent techniques designed for the two above mentioned issues does not effi- ciently deal with the issues at once, because achieving storage efficiency contradicts with the deduplication of authentica- tion tags. In [18], public auditing with a deduplication scheme based on homomorphic linear authentication tags was proposed. Each user has to generate the integrity tags, even for the file in the cloud. Moreover, the file is available in its plain form on the cloud side. Li et al. [12] proposed an integrity auditing scheme for encrypted deduplication storage.

This scheme is based on homomorphic verifiable tags and Merkle hash tree. A user encrypts his file by using a convergent encryption technique and uploads the file to a fully trusted TPA.

#### **III.THE PROPOSED SCHEME**

Here, we describe the system model of our scheme. We also give the corresponding security model. After that, we will give a detailed description of our scheme according to the models.

#### A. SYSTEM AND SECURITY MODEL

Our scheme utilizes the BLS signature-based Homomorphic Linear Authenticator (HLA), which was proposed in [14], for integrity auditing and secure deduplication. We also intro- duce TPA to support public integrity auditing. The proposed scheme consists of the following entities.

· Client (or user).

Outsources data to a cloud storage. CE-encrypted data is first generated, and then uploaded to the cloud storage to protect confidentiality. The client also needs to verify the integrity of the outsourced data. To do this, the client delegates integrity auditing to the TPA.

#### • Cloud Storage Server (CSS).

Provides data storage services to users. Deduplication technology is applied to save storage space and cost. We consider that the CSS may act maliciously due to insider/outsider attacks, software/hardware malfunc- tions, intentional saving of computational resources, etc [13]. During the deduplication process, the CSS carries out the PoW protocol to verify that the client owns the file. Moreover, in the integrity audit process, it is necessary to generate and respond to a proof corre- sponding to the request of the TPA.

• TPA (Third Party Auditor).

Performs integrity auditing on behalf of the client to reduce the client's processing cost. Instead of the client, the auditor sends a challenge to the storage server to periodically perform an integrity audit protocol. TPA is assumed to be a semi-trust model, that is, an honest but curious model. Under the assumption, it is assumed that the TPA does not collude with other entities.

The relation between entities can be seen in Fig. 1. A client and a CSS perform PoW for secure deduplication, and a TPA is placed between the client and the CSS to execute integrity auditing instead of the client.

Here, we consider the following types of adversary models: outside adversary, insider adversary CSS, and semi-honest adversary TPA.

• Outside adversary: Assuming that the communication channel is not secure, an outside attacker can easily inter-

cept the transmitted data. An outside attacker attempts to pass the PoW process as if it were the proper owner of the data. Insider adversary CSS: The CSS assumes that it can act maliciously. It attempts to get information out of the

### Vol. 7, Issue 7, July 2019

FIGURE 1. System model.

user's encrypted data, and modify or delete the user's data.

• Semi-honest adversary TPA: The TPA is assumed to perform the protocol correctly; however, in the pro- cess it tries to obtain information about the user's data.

In addition, the proposed scheme should satisfy the following security objectives.

• Privacy: Except for the information about duplication, no information about the outsourced data is revealed to an adversarial party.

Secure deduplication: Secure deduplication is supported without revealing any information except for the information about duplication.

• Public verifiability: The TPA is able to examine the accuracy and availability of the outsourced data without querying the entire data and without intervention by the data owner.

• Storage correctness: If the CSS is keeping the user's data intact, it can pass the TPA's verification.

**B. DETAILED OPERATION OF THE PROPOSED METHOD:** The proposed scheme does not compute authentication values separately for a proof of the PoW process and for a proof of the integrity auditing; instead, it computes only one authen- tication value depending on the duplication. The proposed scheme uses the BLS signature based homomorphic authen- ticator [14] to generate the authentication value to provide secure deduplication and public integrity auditing. Let e G G  $G_T$  be a computable bilinear map with group G's support being  $Z_p$  for some large prime p. g is a generator of

G, and BLSHash :  $\{0, 1\}^* \rightarrow G$  is the BLS hash [3]. A user

chooses a random  $\alpha Z_p$ , and computes  $v g^{\alpha}$  (G). The user's private key is sk  $\alpha = \frac{1}{2}$  and the public key is pk v  $\in$  The user also generates (spk, ssk) to digitally sign a file using a cryptographically secure signature scheme such as RSA PSS; or DSA. It is assumed that the public key is distributed securely to the entities.

The proposed method includes the following three proce- dures.

• First upload procedure: In this case, a user first uploads a file that is not stored in the CSS. First, a file ID/Tag and a convergent encryption key K are generated, and

(A High Impact Factor, Monthly, Peer Reviewed Journal)

Website: <u>www.ijircce.com</u>

Vol. 7, Issue 7, July 2019

FIGURE 2. First upload procedure. }

the file is encrypted using CE with K and then uploaded to the CSS. The CSS maintains the list of owner, tag, and ciphertext. The user computes an authentica- tion tag for the integrity auditing and sends it to the TPA. =

Subsequent upload procedure: This procedure is per- formed when a duplicate file is uploaded. The CSS checks for the duplication using the file tag, and in the event of duplication, it proceeds with the PoW protocol to examine the ownership of the user. If a user passes this process, the CSS adds the file ownership of the user to the stored file.

existing schemes such as DupLESS [11]; this is omitted in this paper. The client sends the Upload Req message to the CSS including  $U_{ID}$ ,  $T_F$ . The CSS checks if a duplicated file exists using  $T_F$ . If not exists, the CSS performs the First upload procedure by sending the First upload Req message to the client. Then, the client computes the ciphertext CT by encrypting F with the convergent key K. CT  $Enc_K(F)$ , where  $Enc_k()$  is an encryption mechanism such as AES in CTR mode [5] and k is a secret key. We assume that CT is divided into n blocks. The client also computes audit tags

t <sup>n</sup> to periodically run the integrity audit  $\mathbf{\overline{p}}$ ro- cedure by the TPA. t<sub>i</sub> BLSHash(i) u<sup>CT<sub>i</sub>  $\alpha$ </sup>, where us a CSS, and then CSS stores T, CT,  $\{t\}^n$ , U

generator selected randomly by the client, and CT<sub>i</sub> is

required to ensure that the files stored on the CSS are fully and intactly maintained. To reduce the user overhead, the TPA performs periodic integrity audits.

the i-th ciphertext block. The client replies CT,  $\{t_i\}^n \sum_{i=1}^{\infty}$  to To do this, the TPA first chooses a random challenge and it sends it to the CSS. The CSS responds by generating a corresponding proof using the stored file. Then the TPA verifies that the response is valid and completes the integrity audit.

### Vol. 7, Issue 7, July 2019

#### 1) FIRST UPLOADPROCEDURE

Let us consider the case where a client  $U_{ID}$  uploads F to CSS. To do this, he should first generate a convergent key K and a file ID  $T_F$ . This process can be performed using client. The client sends the Audit Info message including  $T_F$ ,  $U_{ID}$ , u, n,  $Sig_{CSS}(T_F, U_{ID})$  to the TPA. The client keeps only  $(T_F, n)$  and deletes the other information. Fig. 2 shows the First upload procedure.

One consideration here is the management of the conver- gence key K. The convergence key K may be stored securely by each client individually. Alternatively, it can upload ek  $Enc_{mk}(K)$ , which is encrypted using the secret master key mk of each client, to the CSS. In this case, the client only needs to keep mk secret. However, the CSS should store ek of = each user for the duplicate file.

FIGURE 3. Integrity auditing procedure.

#### 2) INTEGRITY AUDITING PROCEDURE

The TPA periodically checks the integrity of the data stored in  $ek^{J=}Enc_{mk}J(K)$ , encrypted using its secret master key mk<sup>J</sup>, to the CSS.

The CSS replies to the Audit\_Res message with  $\mu$ ,  $\tau$ . The TPA verifies the proof as follows:

$$e(\mu,g) == e^{-\frac{\Sigma}{BLSHash(i)^{v_i} \cdot u^{\tau_i}}}, v .$$

(3) Fig. 3 shows the Integrity auditing procedure.

#### SUBSEQUENT UPLOAD PROCEDURE

If the CSS has already stored the same file, the Subsequent upload procedure is performed for the deduplication (see Fig. 4). To verify the ownership of the client  $U_{ID}J$ , the CSS runs the PoW protocol. To do this, the CSS generates the challenge values  $Q = I_i(v_i)$ , where I is a random subset of the set [1,n] and  $v_i$  is a random element selected in  $Z_p$ . The CSS sends the PoW Chall message with (u, Q) to the client. Then, the client derives the corresponding  $P^{roof} = \{ \}_{values} \}_{values} BLSHash(i) u^{CT} i_{vv} \alpha^{J}$  for each

 $\in$  i I, and then computes  $(i v) \in O_i$   $(i v) \in O_i$

#### Vol. 7, Issue 7, July 2019

#### IV. ANALYSIS

The proposed scheme satisfies the security objectives men- tioned above. From the privacy perspective, the proposed method outsources the encrypted ciphertext to the CSS using the convergent encryption key. In the integrity auditing pro- cess, the TPA can also partially obtain the information about the ciphertext. Assuming that the convergent key generation process is performed through the OPRF (oblivious pseudo random function) protocol with the trusted key server as in DupLESS [11], it provides security against offline brute- force attacks. An attacker who does not obtain the convergent key K cannot get any information from the outsourced ciphertext, except the information of duplication. The pro- posed scheme also supports secure deduplication by provid- ing deduplication for the ciphertext and performing the PoW protocol. This also depends on the security of the convergent key, as mentioned above, and the security of BLS signature based HLA [14].

The TPA then audits the integrity of the data without user intervention. It depends on the security of the BLS-based

FIGURE 4. Subsequent upload procedure with PoW.

homomorphic authentication tag, and its security has been analyzed in [14]. Thus, the proposed scheme supports public verifiability. Finally, if the CSS keeps the data intact, it can pass the verification by the TPA. This is also provided by the security of the BLS-based homomorphic authentication tag used, thus ensuring the correctness of the storage.

In order to provide a comparison with the existing schemes, first, the scheme proposed in [18] is considered. This scheme supports integrity auditing and deduplication using a polynomial-based authentication tag and a homomorphic lin- ear tag. During the setup process, the user computes a homo- morphic linear tag and uploads it to the cloud server. Then, the TPA performs integrity auditing with the cloud server through the interaction using a polynomial-based authentica- tion tag. In the deduplication process, when the cloud server randomly selects a set of block indexes for the PoW, the server sends them to the user. Then, the user transmits the corresponding plaintext blocks as the response. Then, the cloud server verifies the file ownership by verifying the validity of the received

(A High Impact Factor, Monthly, Peer Reviewed Journal)

Website: <u>www.ijircce.com</u>

### Vol. 7, Issue 7, July 2019

blocks using the pairing operation.

The biggest problem with this scheme is that the data is used as a plain text on the cloud side; therefore, it does not support secure deduplication. In addition, regardless of the file duplication, users always have to compute authentication tags. This results in a high computational overhead.

In the scheme proposed in [12], the client uploads a file to a TPA that is assumed to be honest. This is a very strong assumption, since most of TPAs in the existing public auditing-related papers are assumed to be semi-honest. It also wastes the bandwidth on the client side, because it always transmits the file to the TPA. When the client uploads the file to the TPA, the TPA computes a homomorphic signature for integrity auditing and uploads it to the cloud server along with the file.

The proposed scheme improves the problems of the above two methods. Table 1 shows the comparison with the existing schemes. The TPA of the proposed scheme is assumed to be semi-honest, and also does not upload the file to the TPA. In addition, the proposed method supports deduplication and integrity auditing for the encrypted data, and the client only

TABLE 1. Comparison with existing schemes.

	Secure deduplication	Privacy-preserving public auditing	Efficiency
[18]	X (because of available in its plain form on CSS)	0	Require two different authentication tags for PoW and for auditing, respectively, regardless of duplication.
[12]	0	X (because the file is up- loaded to TPA)	Loss of bandwidth advantages in the client side
Proposed scheme	0	0	Require a computation of only one tag of both authentication tags, and ensure bandwidth advan- tages in the client side

### Vol. 7, Issue 7, July 2019

needs to perform a single authentication tag computation. It has similar computational overhead in each case of the first upload and duplicate upload. That is, in the case of the first upload, the authentication tag for the integrity audit is computed, and in the case of deduplication, the authentication tag for the PoW is generated. Therefore, it provides better efficiency than the existing schemes in the viewpoint of client-side computational overhead.

### I. VARIANCES

In Section III, we designed a new secure deduplication sup- porting public auditing, and proved its security and efficiency in Section IV. The proposed scheme is secure under a rea- sonable security model and its performance is better than the existing schemes as shown in Section IV. Here, we pro- vide some techniques to achieve greater security and better performance.

FIGURE 6. Subsequent upload process for improving the computational overhead on the client side.

A. IMPROVEMENT FROM THE VIEWPOINT OF SECURITY In this section, we will consider a slightly stronger attack scenario, which was not considered in Section IV. Recall that we assumed the original data holder to be a reliable entity who behaves honestly. Hence, we used the assumption to analyze the proposed scheme. However, in this section, we discuss a possible attack scenario, which can be performed by the valid user who is a legitimate data holder, and

(A High Impact Factor, Monthly, Peer Reviewed Journal)

Website: <u>www.ijircce.com</u>

### Vol. 7, Issue 7, July 2019

provide a countermeasure for the attack by slightly modifying the scheme in Section III.

Recall that the proposed model described in Section III uses the same generator u to generate the authentication tag for integrity verification and the authentication tag for PoW. In the case of the duplicated upload, it may be possible to attack the server in PoW process by acquiring the authenti- cation tag of the already uploaded file and using it to pass the ownership proof procedure. When the adversary is an outsider who cannot easily obtain the tag, it is not easy to mount the attack. However, if the original data holder helps an adversary to obtain the authentication tag, it is easy to mount the attack. As recognized in [8], the original file holder can utilize the storage service as a content distribution network, and this could be a threat to storage services. Hence, if we consider such a stronger adversary, we need a countermeasure to prevent a legitimate user from helping others to obtain the stored data.

Note that it is not possible to prevent the data holder from giving his data to others, and therefore the goal of the countermeasure is to make it difficult for an adversarial user to use the storage service as a content distribution network. As a concrete countermeasure to alleviate this threat, we can consider a random selection of a generator for each PoW

process. The CSS randomly chooses a generator u<sup>J</sup> and sends

it to the client as the PoW Chall message. Then, it is possi- ble for the CSS to perform more secure PoW by verifying whether an appropriate response is returned by the client. Even though the original file holder can still help other users to obtain the ownership, the user should have the entire file and perform costly operations to do so. Hence, in the data holder's viewpoint, it is better to give the file to the adversary instead of helping the adversary to pass the PoW procedure. Fig. 5 shows the Subsequent upload process with improved security.

In the case of a duplicate file upload, the CSS performs the PoW process. To do this, the CSS chooses a random generator  $u^{J}$  and challenge values  $Q = \{I, (v_i)\}$ , where the challenge Q is generated as in Section III. The CSS sends the PoW Chall message with  $(u^{J}, Q)$  to the client. Then, the client returns the corresponding proof values  $(\mu, \tau)$  computed by using the generator  $u^{J}$  and its own public key  $\alpha^{J}$ . The CSS verifies the proof with  $u^{J}$  and the client's public key  $v^{J}$  by checking whether the following holds;

$$e(\mu, g) == e BLSHash(i)^{v_{1}} \cdot \mu^{J_{1}}, v^{J} \Sigma$$

After obtaining the ownership, the client and the CSS use the same generator u to perform the integrity auditing. However, it does not a matter anymore since the client cannot help others by using the values to pass the PoW to obtain the ownership of the file F.

A. **IMPROVEMENT FROM THE VIEWPOINT OF EFFICIENCY:** At present, a variety of devices are used to generate and use data in storage services. Though the capability of the devices has improved more than ever before, we still need to design light schemes for storage services due to the increase in size of data. In this viewpoint, we design a technique that can permit a client to pass some costly operations to the CSS in the upload procedure.

To reduce the computational complexity, as shown in Fig. 6, the process of uploading duplicate files can be modified. The client uploading the duplicate file computes only the authentication tag  $\tau$  for each CT<sub>i</sub>, unlike in Section III. That is, the client does not compute  $\mu$  and sends the PoW Res message with only the proof  $\tau$  to the CSS. Then, the CSS computes  $\mu$  and verifies  $\tau$ .

This reduces the amount of computation on the client side, while the CSS's computational overhead increases relatively. However, when the client is a lightweight device such as a mobile device it is advantageous to transfer a part of the computation to the CSS, which has a a higher performance than the client. Moreover, we can implement the online step by choosing Q I,  $(v_i)$  and pre-computing  $\mu$  before a subsequent upload process is initiated by a new client. If we apply the pre-computation technique, we can reduce the com- putational complexity without increasing the cost for the CSS in the online step.

#### Vol. 7, Issue 7, July 2019

#### V. CONCLUSION

When storing data on remote cloud storages, users want to be assured that their outsourced data are maintained accurately in the remote storage without being corrupted. In addition, cloud servers want to use their storage more efficiently. To satisfy both the requirements, we proposed a scheme to achieve both secure deduplication and integrity auditing in a cloud environment. To prevent leakage of impor- tant information about user data, the proposed scheme supports a client-side deduplication of encrypted data, while simultaneously supporting public auditing of encrypted data. We used BLS signature based homomorphic linear authen- ticator to compute authentication tags for the PoW and integrity auditing. The proposed scheme satisfied the secu- rity objectives, and improved the problems of the existing schemes. In addition, it provides better efficiency than the existing schemes in the viewpoint of client-side computational overhead. Finally, we designed two variations for higher security and better performance.

Vol. 7, Issue 7, July 2019

T. SujiLatha has received her M. Tech. in Computer Science from JNTU, Anantapur. She is dedicated to teaching field from the last 9 years. She has guided 10 P. G. and 30 U. G. students. Her research areas included in Networking and cloud Computing. At present she is working as Associate Professor in Gokula Krishna College of Engineering, Sullurpet, SPSR Nellore (DT) Andhra Pradesh India.
