Assistant Professor, Dept. of Computer Science, Desh Bhagat University, Punjab, India<sup>2</sup>

**ABSTRACT:** Due to the absolute amount of opinion loaded web assets such as debate meeting, analysis site, blogs and reports corpora existing in digital structure greatly of the existing study is focus on the region of sentiment analysis. People are planned to extend a structure that can classify and organize opinion or sentiment as represent in an electronic content. In this we tested on movie reviews, product reviews and Facebook comments. The consequences illustrate that a fusion arrangement can recover the organization value. In this paper, we calculate the pros and cons of the existing technique and improve the existing techniques with POS tagging and generate the score of the comments or words and predict the sentiment of the comment and then the conclusion is devised.

**KEYWORDS:** Natural language processing, sentiment analysis, Linguistic rules, POS tagging, opinion mining.

### I. INTRODUCTION

Nowadays, an enormous amount of information is existing in online documents. In the middle of the numerous types of information accessible, one valuable type is the sentiment, or opinions people express towards a subject. The prospect to confine the opinions of the common public regarding public actions, political activities, business strategy, promotion campaign, and product preferences has raise growing awareness mutually in the technical society, for the thrilling open challenge, and in the industry globe for the significant fallouts in advertising and economic calculation. The ever-growing quantity of unstructured information on the network, still, is a difficult assignment and requires rapid and proficient model for opinion mining.

Opinion mining is the study that analyzes people's opinion, sentiment, evaluation, appraisal, attitude, and emotion towards entities such as products, services, organizations, individuals, issues, events, topics, and their attributes. These methods usually try to mine the overall sentiment exposed in a document, either good or bad, or wherever in between. A significant amount of research has already been carried out to categorize sentence into various categories of emotion. The emotions that have been worked upon are either positive or negative or finding the polarity. Sentiment that express an attractive situation (e.g., the picture is flawless.) has positive polarity, as one representing an adverse situation (e.g., the product fails to meet our quality expectations.) has negative polarity. Further adjectives, other substance words such as nouns, adverbs, and verbs are also worn to convey sentiments. A few verbs do not indicate sentiment by themselves; however only relocate sentiments between their opinions. Sentiment words with adjectives, adverbs, and nouns are able to basically distinct as either positive or negative in terms of polarity.

Sentiment analysis use sentiment terms clear in the sentiment lexicon and sentiment patterns in the sentiment pattern database. There has been large learning on routine text analysis for sentiment, such as sentiment classifiers, affect analysis, automatic survey analysis, and opinion extraction, or recommender systems. These methods usually try to mine the overall sentiment exposed in a document, either good or bad, or wherever in between. . Two challenging aspect of sentiment analysis is: First, while the on the whole opinion regarding an area is valuable, it is only a division of the information of significance. Document stage sentiment categorization fail to identify sentiment about individual aspect of the subject.

Second, the relationship of the extract sentiment to a definite matter is hard.

In order to recognize sentiment terms and evaluate their semantic interaction with the subject phrase, natural language processing plays a vital role. POS tagging allow us to disambiguate several polysemous terms such as “like,” which denote sentiment just when used as a verb instead of as an adjective or preposition. Syntactic parsing allows us to discover associations linking sentiment terms and the subject term.

The rest of the paper is organized as follows: Section 2 presents review of related work in the field of opinion mining and sentiment analysis; Section 3 describes the objectives of related work; Section 4 illustrates the proposed methodology; Section 5 presents the results; finally, Section 6 concludes the paper and suggests directions for future work.

## II. REVIEW OF RELATED WORK

**Padmaja and Fatima[1]** This paper will aim to focus on the vital definition of Opinion Mining, analysis of linguistic resources required for Opinion Mining, few machine learning techniques on the origin of their procedure and significance for the study, estimation of Sentiment classifications and its assorted application.

**Haseena Rahmath [2]** extract the constructive satisfied from these opinion sources become a difficult task. These circumstances produced a new region of research called opinion mining and sentiment analysis. Opinion mining and sentiment analysis extract and classify the people’s opinion automatically from the internet. This paper discusses various application and challenges related to the Opinion Mining and Sentiment Analysis.

**Osimo and Mureddu [3]** the aim of this paper is to present an outline for discussion upon a new Research Challenge on Opinion Mining and Sentiment Analysis. This research challenge has been developed in the scope of project CROSSOVER “Bridging Communities for Next Generation Policy-Making” in the view of the definition of a new Research Roadmap on ICT Tools for Governance and Policy Making, building on the model and the research roadmap developed within the scope of the CROSSROAD project<sup>3</sup>, but with a stronger focus on governance and policy modeling.

**Prabowo, Thelwall [4]** this paper combines rule-based classification, supervised learning and machine learning into a new combined method. This method is tested on movie reviews, product reviews and MySpace comments. The results show that a hybrid classification can improve the classification effectiveness in terms of micro- and macro-averaged  $F1$ .

**Vinodhini, Chandrasekaran [5]** People are intended to develop a system that can identify and classify opinion or sentiment as represented in an electronic text. An accurate method for predicting sentiments could enable us, to extract opinions from the internet and predict online customer’s preferences, which could prove valuable for economic or marketing research. Till now, there are few different problems predominating in this research community, namely, sentiment classification, feature based classification and handling negations.

**Alec Go, Bhayani, and Huang [6]** we introduce a novel approach for automatically classifying the sentiment of Twitter messages. These messages are classier as either positive or negative with respect to a query term. This is useful for consumers who want to re-search the sentiment of products before purchase, or companies that want to monitor the public sentiment of their brands. There is no previous research on classifying sentiment of messages on microblogging services like Twitter. We present the results of machine learning algorithms for classifying the sentiment of Twitter messages using distant supervision.

## III. PROPOSED METHODOLOGY

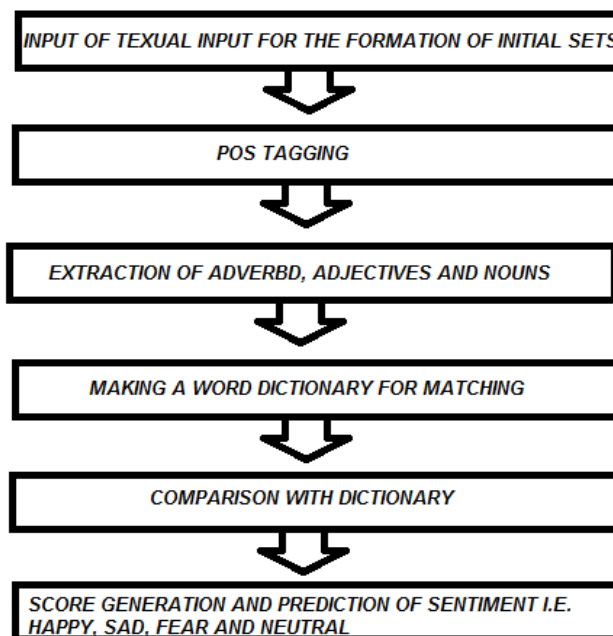

A detailed literature survey on sentiment analysis and emotion mining algorithms will be conducted to find the pros and cons of the existing algorithms. Also a literature study will be conducted on the other mining algorithms based on the

# International Journal of Innovative Research in Computer and Communication Engineering

(An ISO 3297: 2007 Certified Organization)

Vol. 3, Issue 9, September 2015

knowledge based or learning based solutions. The best sentiment analysis algorithm out of all of the surveyed ones would be used for the purpose of the new sentiment analysis solution. A series of basic social datasets will be prepared which will be used to conduct all of the experiments on the proposed model implementation. Afterwards, the simple sentiment analysis system would be developed, which will work with single word fetching and evaluation to produce the emotion mining results. Then the two word and three word combination evaluation models would be developed using the latter as the base of the sentiment analysis solution. Then the model would undergo a debugging process and the results would be obtained and analyzed as the last step of the research.

The following figure represents the diagram of the proposed system. Proposed model has the following stages:-

1. First the user has to enter the input of textual input for the formation of initial sets.
2. Then POS Tagging is performed.
3. By doing POS Tagging we can get the noun, adverb, adjective etc.
4. Then we make the word dictionary for matching all words.
5. Then we compare the words or noun, adverb and adjective with dictionary and generate the score of all the words and predict the sentiment of the input i.e. Happy, Sad, Fear and Neutral.

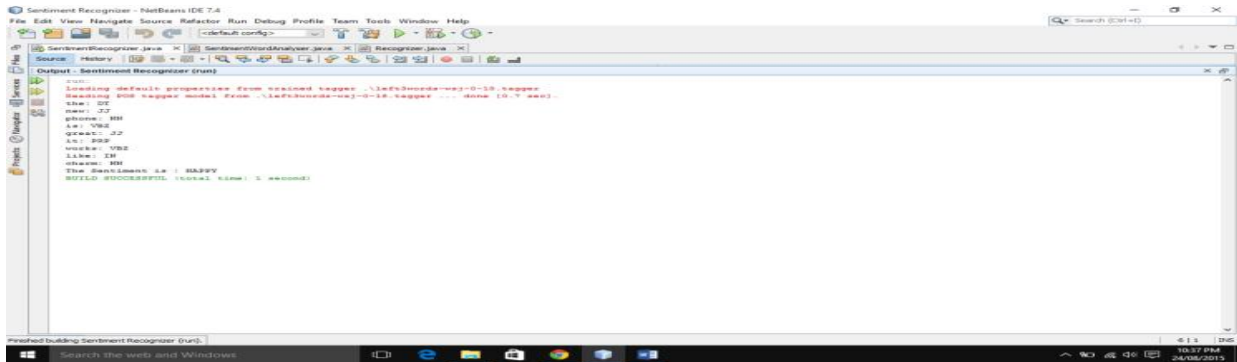

## IV. RESULTS

For Sentiment Analysis System, we used JAVA programming language to program Sentiment Analysis System. We used dictionary files for 4 emotion types: Happy (or Positive), Sad & Fear (or Negative) and Neutral. To cover up everything, we also defined a class of Unknown Sentiment which is classified when the sentiment does not match any of the above sentiment. The program also used a third party tool called Stanford Core NLP's POS Tagger. This library is used for Part of Speech Tagging.

Vol. 3, Issue 9, September 2015

```
run:
Loading default properties from trained tagger .\left3words-wsj-0-18.tagger
Reading POS tagger model from .\left3words-wsj-0-18.tagger ... done [0.9 sec]
i: DT
w: JJ
ghost: NN
almost: RB
cried: VBN
out: IN
of: IN
fear: NN
The Sentiment is : POSITIVE
BUILD SUCCESSFUL (total time: 1 seconds)
```

A running sample of the Code

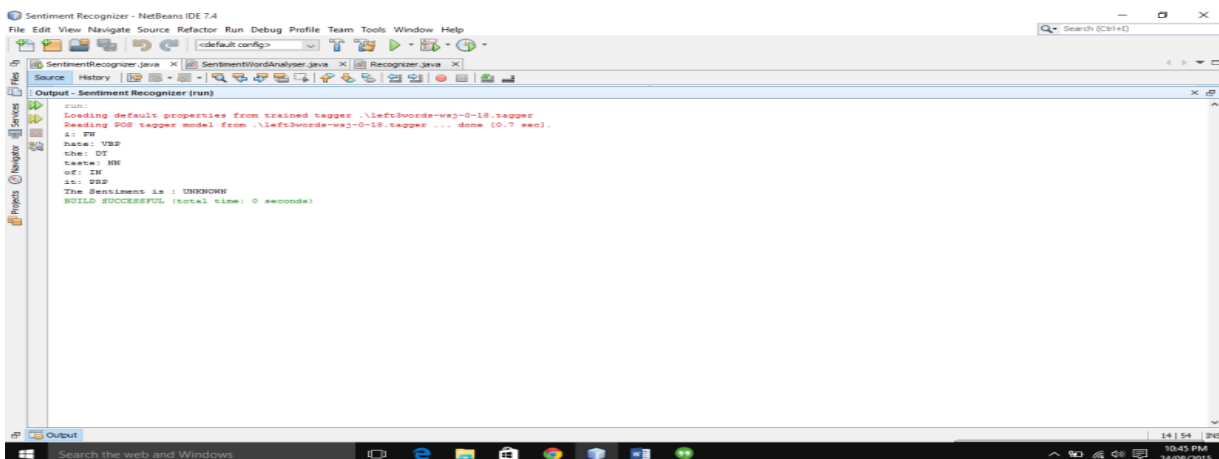

This code runs and reads the sentence given to it. It then extracts the Nouns, Adjectives, Adverb and then uses the dictionary to predict the sentiment. Based on the weight values of each dictionary result, the sentiment is predicted. In the above case, the actual comment is a positive response and it does come out as positive.

```
run:
Loading default properties from trained tagger .\left3words-wsj-0-18.tagger
Reading POS tagger model from .\left3words-wsj-0-18.tagger ... done [0.7 sec]
i: DT
w: VBD
a: DT
ghost: NN
almost: RB
cried: VBN
out: IN
of: IN
fear: NN
The Sentiment is : FEAR
BUILD SUCCESSFUL (total time: 0 seconds)
```

Another sample “Last night I saw a ghost. I almost cried out of fear”. Predicted as FEAR

In the above example a sentiment FEAR(negative) is correctly predicted based on the analysis of the words and the dictionary weight value.

```
run:
Loading default properties from trained tagger .\left3words-wsj-0-18.tagger
Reading POS tagger model from .\left3words-wsj-0-18.tagger ... done [0.7 sec]
i: TW
w: VBD
t: DT
taste: NN
of: IN
it: PPP
The Sentiment is : UNKNOWN
BUILD SUCCESSFUL (total time: 0 seconds)
```

A failed result. “I hate the taste of it. Bad!” Predicted as UNKNOWN

# International Journal of Innovative Research in Computer and Communication Engineering

(An ISO 3297: 2007 Certified Organization)

Vol. 3, Issue 9, September 2015

There is a failed example of the system. Here the actual sentiment was SAD (or negative) but is predicted as UNKNOWN. Mainly, if the number of words are not much (like here), the system confuses and generally throws an UNKNOWN prediction.

```
run:
Loading default properties from trained tagger .\left3words-wsj-0-18.tagger
Reading POS tagger model: zcom .\left3words-wsj-0-18.tagger ... done [0.7 sec].
it: PRP
is: VBZ
getstate: JJ
waste: NN
of: IN
time: NN
do: VBP
not: RB
even: RB
buy: VB
this: DT
product: NN
The Sentiment is : SAD
BUILD SUCCESSFUL (total time: 0 seconds)
```

Another Success. "It is pathetic. Waste of time. Do not ever buy this product". Predicted as SAD (or negative) Since, our system can only predicts between Happy or Positive, Sad or Negative, Fear and Neutral. So, anger or a bad review is always predicted as SAD.

## V. CONCLUSION

In this paper, we have developed a Sentiment Analysis System and we used Score based analysis to predict the sentiment of a user from his/her comments. The System is quantitatively tested and the results are produced. The system has difficulty in predicting the sentiment if the sentence is very small or has a few words in it. With a fair size of 3 sentences text is predicted very accurately.

## VI. FUTURE SCOPE

The future scope of this project is to analyze more complicated text like sarcasm by extracting named entity and matching it with the name of current product/service in consideration. Our current project does so but only by looking at the pronouns. We can extend it to named entity also and thus a more intelligent system can be realized
