Assistant Professor, Dept. of ECE., Lakshmi Narain College of Technology Excellence, Bhopal, India

ABSTRACT: Routing is the process of selecting a path for traffic in a network or between or across multiple networks. Broadly, routing is performed in many types of networks, including circuit-switched networks, such as the public switched telephone network (PSTN), and computer networks, such as the Internet. Due to the high mobility feature of VANET, the use of correct routing protocol is of great concern. Due to highly challenging nature of VANET, the researcher came out with different types of protocols. This paper reviews about various routing protocols and routing scheme.

KEYWORDS: Routing, Protocol, PSTN, Network, Internet.

I. INTRODUCTION

A routing protocol indicates how switches speak with one another to disperse data that empowers them to choose courses between any two hubs on a PC arrange. Switches play out the "traffic coordinating" capacities on the Web; information parcels are sent through the systems of the web from switch to switch until they arrive at their objective PC. Routing calculations decide the particular decision of course. Every switch has an earlier information just of systems connected to it straightforwardly. A routing protocol shares this data first among quick neighbors, and afterward all through the system. Thusly, switches gain information on the geography of the system. The capacity of routing protocols to powerfully conform to changing conditions, for example, debilitated information lines and PCs and course information around hindrances is the thing that gives the Web its adaptation to non-critical failure and high accessibility.

The particular attributes of routing protocols remember the way for which they abstain from routing circles, the way wherein they select favored courses, utilizing data about bounce costs, the time they require to reach routing intermingling, their adaptability, and different factors, for example, transfer multiplexing and cloud access system boundaries. Certain extra attributes, for example, multilayer interfacing may likewise be utilized as a methods for disseminating positive systems administration doors to approved ports.[1] This has the additional advantage of forestalling issues with routing protocol circles..

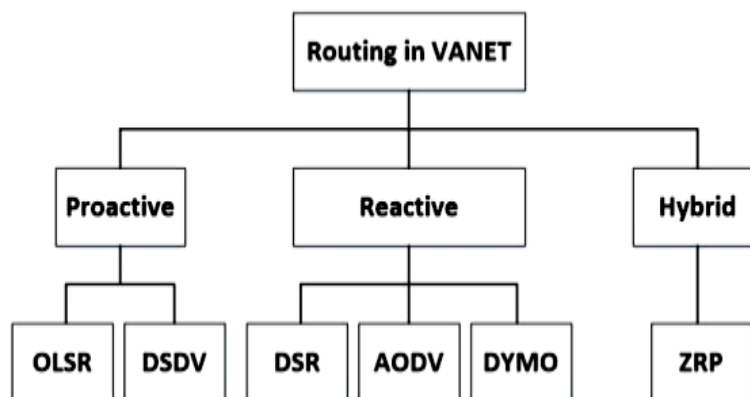

Figure 1: Classification of Ad-hoc Routing Protocols

Proactive Protocols

- The protocols keep on computing the route regularly and therefore, the routing table changes or updates frequently. These protocols use Bellman Ford Algorithm in which all the nodes keep the information related to the next node.

- The one of the advantage of the said protocol is that the route will be known whenever a packet wants to send a data. Example of this protocol includes Optimized Link State Routing (OLSR) and Destination Sequenced Distance Vector (DSDV) protocol. OLSR is basically a refined version of link state protocol.
- The working of link state protocol is such that any change in a topology will be broadcasted to all the nodes in a network which will increase the network overhead. OLSR handles with two kinds of messages like hello and a message to control the topology. Hello messages are used to find the data about the connection status. While topology control message is used to broadcast its own neighbour information with the help of multi point relay (MPR) selected list. Because of the use of MPR, the overload has reduced as it was in the case of pure link state protocol. DSDV protocol is a modification of Bellman Ford Algorithm. This algorithm resolved the problem of looping in routing by maintaining the sequence number information of each node.

Reactive Protocols

- This type of protocols does not possess the information about all the nodes. It only keeps the information of the nodes that comes in the route.
- The example of reactive protocols is an Ad-hoc On-Demand Distance Vector (AODV), Dynamic Source Control Routing (DSR) and Dynamic Manet on Demand (DYMO) protocol. AODV is the most commonly used protocol in VANET.
- It possesses the information of nexthop for the destination nodes. Moreover, each routing table lasts for certain period. If there is no route demand within the specified time than route will get expired and a new route will be defined on demand. As per AODV, whenever a source node wants to send a data to the destination node, it will check the route in its routing table.

Hybrid Protocols

- Hybrid is a composite of proactive and reactive routing protocols which reduced the overhead and delays occurrence due to the periodic sharing of topology information.
- The hybrid approach, the efficiency and scalability feature of network has improved. On the other hand, the drawback of hybrid approach is high latency for navigating new routes. The common protocol based on hybrid approach is Zone Routing Protocol (ZRP).

II. LITERATURE SURVEY

S. Hao et al., [1] The mobile Ad Hoc arrange (MANET) is a self-sorting out and self-designing remote system, comprising of a lot of mobile hubs. The plan of productive routing protocols for MANET has consistently been a functioning territory of examination. In existing routing calculations, in any case, the current work doesn't scale all around ok to guarantee course soundness when the portability and conveyance of hubs change with time. In addition, every hub in MANET has just restricted starting vitality, so vitality protection and equalization must be considered. An effective routing calculation ought not exclusively be steady yet in addition vitality sparing and adjusted, inside the dynamic system condition.

L. Tang et al., [2] One of the difficulties presented by the investigation of vehicular ad hoc networks (VANETs) is the transmission of information gave by esteemed traffic data administrations under deficient connection conditions. Numerous dispersal protocols have been created by the network to tackle the issue. In this study, the creators investigate the administration revelation where information spread should fill in as an establishment. At that point, they propose a diagram and scientific categorization of an enormous scope of information dispersal accessible for VANETs.

P. Verma et al., [3] Occasional broadcast of helpful mindfulness messages (CAMs) is vital considering security related applications, for a system like VANET. This investigation proposes a vehicle-identifier (ID)- based Macintosh conspire for the occasional broadcast of CAMs in a vehicular system. Every CAM created by a vehicle is related with a one of a kind ID. This examination utilizes this quality of CAM messages while taking an interest in the channel appraisal technique. Every vehicle gauges the arbitrary back-off number with the one of a kind ID joined in their individual CAM. This inevitably leads to the determination of a vehicle-ID-based arbitrary back-off number, moderating every single imaginable likelihood of crash because of same back-off number choice. The reenactment is performed considering immersed traffic conditions, to break down its conduct under most basic circumstances. The proposed model disposes of the odds of choosing zero as the underlying back-off number, wiping out any odds of successive freeze process.

M. N. Siraj et al., [4] Patterns in systems administration are moving from circulated to sensibly incorporated networks. Programming characterized organizing (SDN) is the key innovation behind this move. This new paradigm not just demonstrates the simplicity of system the board in wired networks yet additionally results into elegant advancement of systems administration protocols. In addition, remote appropriated networks (WDNs) and programming characterized radios (SDRs) are additionally moving towards the brought together methodology. Be that as it may, because of

dispersed control nature of WDNs, already winning routing calculations can't adapt the plan guideline of concentrated routing calculations.

S. A. A. Ghafourian Ghahramani et al., [5] propose address the exhibition of the 802.11p protocol as far as the packet delivery ratio (PDR) and the packet gathering ratio (PRR) for broadcasting security messages in roadway conditions. With respect to semi-scanty and halfway traffic, we attempt to respond to questions, for example, what are the upper, prevailing and lower limits of PDR and PRR in each rush hour gridlock condition? How they may digress from their normal qualities? what's more, What division of vehicles may experience such limits? To respond to such inquiries, we propose to consider the correspondence diagram framed among vehicles as an uncommon sort of the perplexing networks and we apply the as of late proposed compulsory connection ruleto combine such system structures.

M. D. P. et al., [6] propose educe harmonics and improve power quality, Hybrid Active Power Filter (HAPF) or shunt HAPF can be employed. The power improvement can be done using various algorithm like RLS algorithm, DC link voltage controller, fuzzy logic based hybrid filter.

X. Li et al., [7] RSU to record the meeting data and broadcast it to the OBUs. This technique maintains a strategic distance from the multi-channel shrouded terminal issue. A logical model is created to assess the total throughput on SCHs. This model thinks about the accompanying elements: non-wellbeing message transmission likelihood in each simultaneous span, normal size of the non-security message, and the quantity of OBUs. Besides, the necessity of acquiring the most extreme throughput is figured. Reenactment results are given to approve the logical model and to show the improvement in throughput.

C. Wu et al., [8] It is hard for these protocols to accomplish a superior and to work appropriately under different situations. In this paper, we initially examine the difficulties of routing in VANETs dependent on the information procured from genuine analyses and afterward propose a routing protocol that can get familiar with the best transmission boundaries by associating with nature. The protocol considers numerous measurements, explicitly information transmission rate, vehicle development, and course length. We utilize both certifiable analyses and PC recreations to assess the proposed protocol.

D. Tian et al., [9] In the multi-bounce and dynamic geography networks, assembling and keeping up a course is testing. To spread data among the vehicles and the foundations productively, a position-based clustering multi-jump routing technique is proposed. The strategy progressively composes VANETs dependent on the serious learning Hebb neural system, which parcels the vehicles into clusters, and these clusters are spoken to by virtual bunch heads. The technique is assessed utilizing NS2 and contrasted and run of the mill ad hoc routing protocol Ad hoc On-Request Separation Vector, Separation Routing Impact Calculation for Portability. The recreation results demonstrate that the strategy is proficient.

M. Chuang et al., [10] Profound purposes the broadcast storm issue, accomplishes low dispersal delay, and gives high dependability over a practical multi-path turnpike situation. The system conveys crisis messages to a particular region (e.g., the zone before the exit) in an ideal way and ensures that every single important vehicle around there will get the messages. Drivers would then be able to change their courses and abstain from getting trapped in a gridlock. Execution assessments by means of NS-2 reproductions show that Profound accomplishes both lower scattering delay and higher unwavering quality than existing methodologies.

Table 1: Summary of literature survey

Sr No	Author Name & Year	Proposed Work	Outcome
1	Z. Khan, IEEE, 2019	A reliable two-layer cluster-based algorithm has been introduced in VANETs to mitigate the link failure problem.	NS-2.35 improves the network parameters such as end-to-end delay and packet delivery ratio compared protocols.
2	M. Khanafer IEEE, 2019	The DWA a backoff algorithm that targets improving the performance of V2R communications in terms of throughput and delay.	Clusters of 20 nodes, the performance in terms of throughput and delay are improved by 32% and 88%, respectively, with DWA.
3	A.Khan, IEEE, 2018	A novel EGT framework to automate the clustering of nodes and nominations of cluster heads, to achieve cluster stability in	The effectiveness and robustness of our proposed EGT approach for different populations and speeds.

		VANETs.	
4	A. Mehood, IEEE, 2018	An intelligent naïve Bayesian probabilistic estimation practice for traffic flow to form a stable clustering in VANET.	The proposed technique has proven to be more strong, stable, robust, and scalable than existing ones.
5	S. A. A. Ghafourian , IEEE, 2017	Apply obligatory attachment rule to synthesize such network structures.	Discussed through comparison with simulation results.

III. CONCLUSION

This paper explores numerous investigations identified with routing protocols. According to the examination finished, AODV end up being the best routing protocol in VANET condition. Besides, video web based is another moving errand to accomplish in VANET. As per the investigation, we have inferred that part of exertion is required to get a decent quality video real time in VANET and AODV again is demonstrated to be better for video applications. In future adaptive routing protocol is designed and implemented for VANET system.
