ABSTRACT: Speech recommendation from ASR is a terribly troublesome task. This paper addresses the issue of keyword extraction from conversations. Using these keywords to retrieve, one significant potentially relevant document and its corresponding speech, this can be recommended to participants. It is difficult to infer precisely the information needs of the conversation participants. In this paper we specify how speech recommended from conversation through ASR output. We first propose an algorithm to extract keywords from the output of an ASR system. Then, we propose a method to derive multiple topically separated queries from this keyword set, in order to maximize the chances of making at least one relevant document when using these queries to search over English Wikipedia. Finally the speech corresponding to the relevant document is recommended to the participants. To the best of our knowledge, this is the first successful research for recommending speech from conversation through ASR output.

KEYWORDS: Natural Language Processing,Keyword Extraction, Ranking,Document Retrieval and Speech Recommendation.

I. INTRODUCTION

People are encompassed by an uncommon abundance of data, accessible as reports, databases, or mixed media assets. Access to this information is conditioned by the availability of suitable search engines, when these are accessible, clients frequently don't start a hunt, in light of the fact that their present movement does not permit them to do as such, or on the grounds that they are not mindful that significant data is accessible [1].

The goal is to maintain multiple hypotheses about users information needs, and to present a recommendation based on the most likely ones. The recommending speech is related to users' current activities. Suppose when users participate in a meeting, their information needs can be modelled as implicit queries that are constructed from the pronounced words, obtained through real-time automatic speech recognition (ASR) [6].

Therefore, aim at extracting a relevant and diverse set of keywords, cluster them into topic-specific queries ranked by importance, retrieve documents, and present participants the most relevant speech from these documents. The topic-based clustering decreases the chances of including ASR errors into the queries, and the diversity of keywords increases the chances of making relevant recommendation, or can lead to a useful speech when following its hyperlinks.

Relevance and diversity can be enforced at three stages: when extracting the keywords; when building one or several implicit queries; or when re-ranking their results. The first two approaches are the focus of this paper. Our recent experiments with the third one [2], show that re-ranking of the results of a single implicit query cannot improve users' satisfaction with the recommended documents.

Proposed system introduces a novel diverse keyword extraction technique [3] from ASR output, which maximizes the coverage of potential information needs of users and reduces the number of irrelevant words. Once a set of keywords is extracted, it is clustered in order to build several topically-separated queries, which are run independently, by using the ranking keywords. The highest rank set is used to retrieve the recommended document. Finally the corresponding speech recommendation is given to the participants.

The following sections, In Section II deals with related work. Sections III introduce proposed method. Section IV relates the result and discussions. Conclusion is summarized in section V. Section VI contains the papers, books, referred during the preparation of this paper.

II. RELATED WORK

Just-in-time retrieval systems have the potential to bring a radical change in the process of query-based information retrieval. Such systems continuously monitor users' activities to detect information needs, and pro-actively retrieve relevant information. To achieve this, the systems generally extract implicit queries (not shown to users) from the words that are written or spoken by users during their activities. In this section, review existing just-in-time-retrieval systems and methods used by them for query formulation. Also discuss previous keyword extraction techniques from a transcript(text).

User interactions with everyday productivity applications (e.g. word processors, Web browsers, etc.) provide rich contextual information that can be leveraged to support just-in-time access to task-relevant information. As evidence for claim, here present Watson [11], a system which gathers contextual information in the form of the text of the document the user is manipulating in order to proactively retrieve documents from distributed information repositories. This system close by describing the results of several experiments with Watson, which shows it consistently, provides useful information to its users.

The AMIDA Automatic Content Linking Device (ACLD) [10] is a just- in-time document retrieval system that constantly retrieves items from a repository and displays them to a participant or to all of them. The repository includes meeting related documents together with excerpts from previous meetings of the group. The device can be used online during a meeting, but also offline, integrated in a meeting browser.

A Speech-based Just-in-Time Retrieval System monitors an ongoing conversation or a monologue and enriches it with potentially related documents, including multimedia ones, from local repositories or from the Internet. The documents are found using keyword-based search or using a semantic similarity measure [9] between documents and the words obtained from automatic speech recognition. Results are displayed in real time to meeting participants, or to users watching a recorded lecture or conversation.

Numerous methods have been proposed to automatically extract keywords from a text, and are applicable also to transcribed conversations. The earliest techniques have used a new keyword extraction algorithm that applies to a single document [8] without using a corpus. Frequent terms are extracted first, and then a set of co-occurrence between each term and the frequent terms, i.e., occurrences in the same sentences, is generated. Co-occurrence distribution shows importance of a term in the document as follows. If probability distribution of co-occurrence between the term a and the frequent terms is biased to a particular subset of frequent terms, then the term a is likely to be a keyword.

On the other hand, manual assignment of high quality keywords is expensive, time-consuming, and error prone. Therefore, most algorithms and systems aimed to help people perform automatic keywords extraction [18] have been proposed. Conditional Random Fields (CRF) [7] model is a state-of-the-art sequence labelling method, which can use the features of documents more sufficiently and effectively. At the
same time, keywords extraction can be considered as the string labelling.

The AMI(DA) system is a meeting room speech recognition system that has been developed and evaluated in the context of the NIST Rich Text (RT) evaluations. Recently, the Distant
Access requirements of the AMIDA project have necessitated that the system operate in real-time. Another more difficult requirement is that the system fit into a live meeting transcription scenario. The AMI system for meeting room recognition is a combination of beam-forming, diarisation and ASR in real time [6].

Several unsupervised approaches [5] were also explores to automatic keyword extraction using meeting transcripts. In the TFIDF (term frequency, inverse document frequency) weighting framework, we incorporated part- of-speech (POS) information, word clustering, and sentence salience score.

Document summarization algorithms are most commonly evaluated according to the intrinsic quality of the summaries they produce. An alternate approach is to examine the extrinsic
utility of a summary [4], measured by the ability of the summary to aid a human in the completion of a specific task. This uses topic identification as a proxy for relevancy determination in the context of an information retrieval task, and a summary is deemed effective if it enables a user to determine the topical content of a retrieved document. It utilize

Amazons Mechanical Turk service to perform a large-scale human study contrasting four different summarization systems applied to conversational speech from the Fisher Corpus.

A new method for keyword extraction from conversations is introduced, which rewards both word similarity, to extract the most representative words, and word diversity, to cover several topics if necessary[3]. Inspired from summarization, the method maximizes the coverage of topics,
those are recognized automatically in transcripts of conversation fragments. The method is evaluated on excerpts of the Fisher and AMI corpora, using a crowd sourcing platform to elicit comparative relevance judgments. The results demonstrate that the method outperforms two competitive baselines.

Enforcing Topic diversity[2] addresses the problem of building concise, diverse and relevant lists of documents, which can be recommended to the participants of a conversation to fulfil their information needs without distracting them. These lists are retrieved periodically by submitting multiple implicit queries derived from the pronounced words. Each query is related to one of the topics identified in the conversation fragment preceding the recommendation, and is submitted to a search engine over the English Wikipedia. Here developed an algorithm for diverse merging of these lists, using a submodular reward function that rewards the topical similarity of documents to the conversation words as well as their diversity.

III. PROPOSED METHOD

A. *Proposed Outline*

The overview of the proposed system is shown in Fig.1.With facilitate of ASR (Automatic speech Recognition) we tend to acknowledge the voice/speech from oral communication and convert it into text format. Then apply keyword extraction strategies to extract keyword from the text,then perform clustering and ranking technique, with the highest ranked keyword, we tend to use Just-in-Time Retrieval Systems[10][11][13] to retrieve data. After completion of document retrieval, we recommend corresponding speech or information to user.

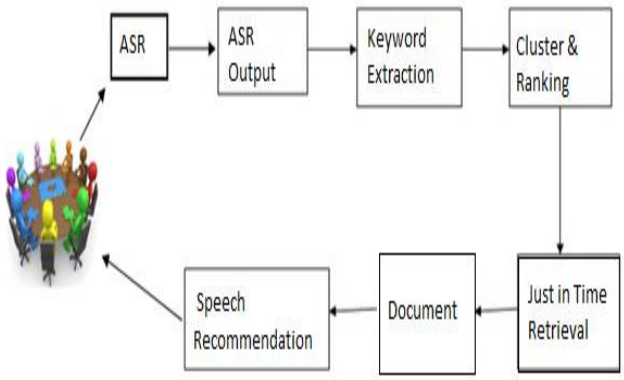

Fig1: Overview of Proposed System.

B. *Automatic Speech Recognition*

Automatic speech recognition (ASR) can be defined as the independent, computer driven transcription of spoken language into readable text in real time. This method begins once a speaker decides what to mention and really speaks a sentence. Then Software produces a speech wave kind that embodies the words of the sentence yet because the extraneous sounds and pauses within the spoken input. Next, the software makes an attempt to decrypt the speech into the simplest estimate of the sentence. Firstly it converts the speech signal into a sequence of vectors that are measured throughout the period of the speech signal. Then, employing a syntactical decoder it generates a legitimate sequence of representations.

C. Diverse Keyword Extraction

We propose to build a topical representation of a conversation fragment, and then select content words as keywords by using topical similarity, while also rewarding the coverage of a diverse range of topics, inspired by recent summarization methods[16][17][19][20]. The benefit of *diverse keyword extraction* is that the coverage of the main topics of the conversation fragment is maximized. So the proposed algorithm will select a smaller number of keywords from each topic.

We aim at extracting a relevant and diverse set of keywords, cluster them into topic-specific queries ranked by importance, and present users a sample of results from these queries. The topic-based clustering decreases the chances of including ASR errors into the queries, and the diversity of keywords increases the chances that at least one of the recommended documents answers a need for information, or can lead to a useful document when following its hyperlinks.

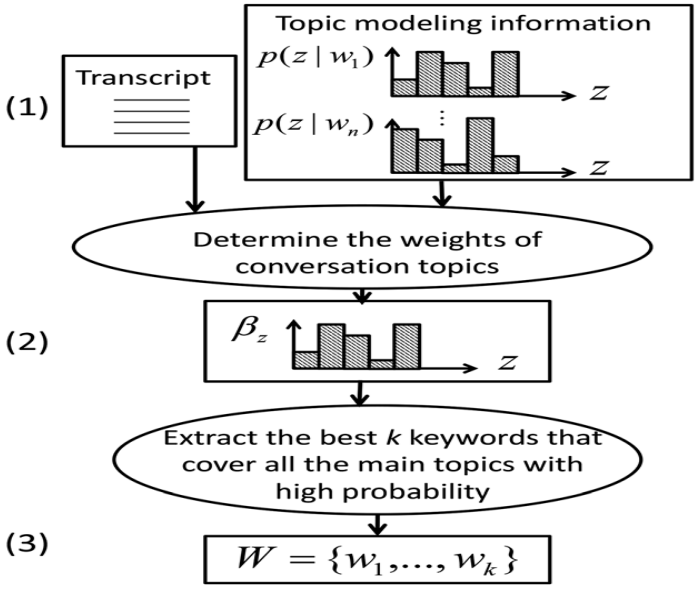

Fig. 2. The three steps of the proposed keyword extraction method: (1) topic modeling, (2) representation of the main topics of the transcript, and (3) diverse keyword selection.

The proposed method for diverse keyword extraction proceeds in three steps, represented schematically in Fig. 2 First, a topic model is used to represent the distribution of the
abstract topic z for each word w noted as $p(z|w)$ depicted in Fig. 2. The abstract topics are not pre-defined manually but are represented by latent variables using a generative topic modeling technique. These topics occur in a collection of documents–preferably, one that is representative of the domain of the conversations. Second, these topic models are used to determine weights for the abstract topics in each conversation fragment represented by β_z . Finally, the keyword list
$W=\{w_1,\ldots,w_k\}$ which covers a maximum number of the most important topics are selected by rewarding diversity, using an original algorithm introduced.

IV. RESULTS AND DISSCUSSION

A. Results

The input contain the oral communication of participants, that are constructed in the background from the pronounced words, obtained through real-time automatic speech recognition(ASR).The output is the most relevant speech of the document that are recommended to the participants . The document is like a Wikipedia Document with all

its unwanted tags is removed and also can download the document. Fig. 3 shows the input, represented as transcript from ASR out and Fig. 4 shows the final speech

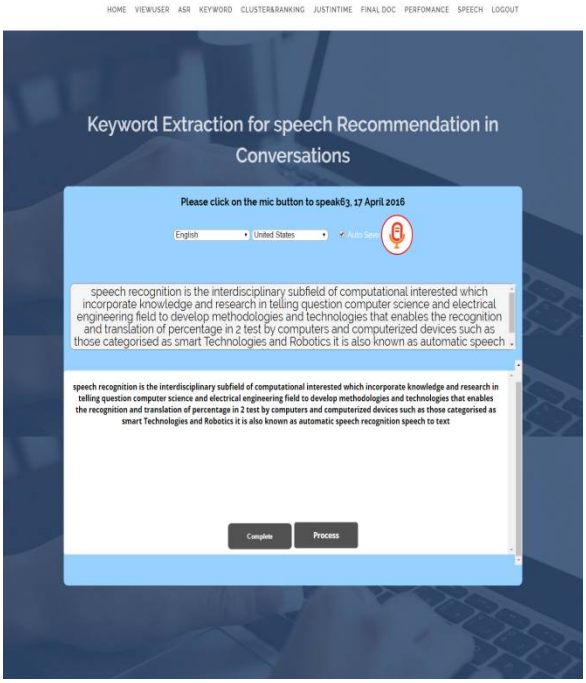

Fig 3.Input Speech

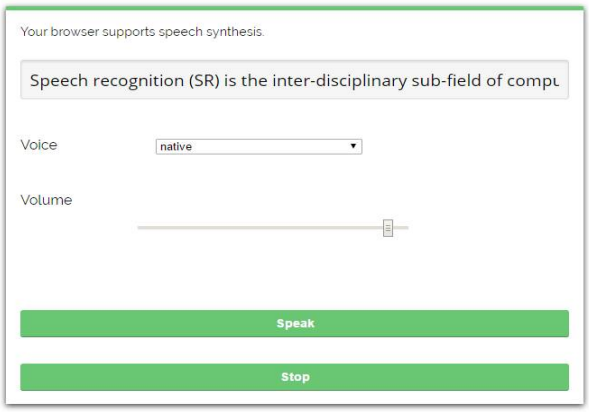

Fig 4. Speech Recommendation

The valid participants can access the previous documents as well as its corresponding speech,with a searching keyword, related to the past meeting transcript. The users can browse the previous document and can access the relevant speech.Also download the document. The user's window is shown in Fig 5 .

V. CONCLUSION

We focused on modelling the users' information needs by deriving implicit queries from short conversation fragments. These queries are based on sets of keywords extracted from the conversation. We have proposed a novel diverse keyword extraction technique which covers the maximal number of important topics in a fragment. Then, proposed a clustering technique to divide the set of keywords into smaller topically-independent subsets constituting implicit queries.

Our current goals are to process also explicit queries, and to rank document results with the objective of maximizing the coverage of all the information needs, while minimizing redundancy in a short list of documents. Integrating these techniques in a working prototype should help users to find valuable documents immediately and effortlessly, without interrupting the conversation flow, thus ensuring the usability of our system.

ACKNOWLEDGMENT

We thank Bodhi Info Solutions and the Idiap Social Computing group for access to the ELEA Corpus. We also acknowledge the anonymous reviewers for their precise comments and insightful remarks that improved the quality and clarity of our submission.
