ABSTRACT: Big data is a new driver of the world economic and societal changes. The world's data collection is reaching a tipping point for major technological changes. This changes leads to a new ways of decision making, managing our health, cities, finance and education. Big data refers to datasets that are not only big, but also high in variety and velocity, which makes them difficult to handle using traditional tools and techniques. In this project we are implementing an effective algorithm for data analysis by extracting features and adapting machine learning approach called ANN. This paper proposed a new technique ANN, which is specifically developed for handling very huge data sets. ANN applies a hierarchical micro-clustering algorithm that accounts the whole data set only once to provide an ANN with high quality samples that carry the statistical summaries of the data such that the summaries maximize the benefit of learning the ANN. ANN tries to generate the best ANN boundary for very huge data sets given limited amount of resources.

KEYWORDS: ANN, Gabor Features, Big data.

I. INTRODUCTION

Big data study is the process of examining huge data items which belongs a varies data types i.e., big data is used to know the hidden patterns, unknown correlations, market analysis, customer choices scale and other useful business informatics. The analytical findings can be helpful in analyzing effective marketing, new revenue opportunities, better customer service, improved operational efficiency, competitive advantages over rival organizations and other business benefits.

The main goal of big data analytics is to support companies make more useful business decisions by enabling data scientists, predictive modellers and other analytics professionals to analyze large volumes of transaction data, which is impossible to handle by human. That could include Web server logs and Internet click stream data, social media content and social network activity reports, text from customer emails and survey responses, mobile-phone call detail records and machine data captured by sensors connected to the Internet of Things.

Some people exclusively associate big data with semi-structured and unstructured data of that sort, but consulting firms like Gartner Inc. and Forrester Research Inc. also consider transactions and other structured data to be valid components of big data analytics applications. Big data can be analyzed with the software tools commonly used as part of advanced analytics disciplines such as predictive analytics, data mining, text analytics and statistical analysis. Mainstream BI software and data visualization tools can also play a role in the analysis process. But the semi-structured and unstructured data may not fit well in traditional data warehouses based on relational databases.

Furthermore,[7] data warehouses may not be able to handle the processing demands posed by sets of big data that need to be updated frequently [7] or even continually for example, real-time data on the performance of mobile applications or of oil and gas pipelines. As a result, many organizations looking to collect, process and analyze big data have turned to a newer class of technologies that includes Hadoop and related tools such as YARN, Map Reduce, Spark, Hive and Pig as well as No SQL databases. Those technologies form the core of an open source software framework that supports the processing of large and diverse data sets across clustered systems.

II. LITERATURE SURVEY

Jianqing Fan et.al in his paper [1] discusses statistical methods for estimating complex correlation structure from large pharmacogenomic datasets. We selectively overview several prominent statistical methods for estimating large covariance matrix for understanding correlation structure, inverse covariance matrix for network modeling, large-scale

simultaneous tests for selecting significantly differently expressed genes and proteins and genetic markers for complex diseases, and high dimensional variable selection for identify important molecules for understanding molecule mechanisms in pharma co genomics. Their applications to gene network estimation and biomarker selection are used to illustrate the methodological power. Several new challenges of Big data analysis, including complex data distribution, missing data, measurement error, spurious correlation, endogeneity, and the need for robust statistical methods, are also discussed.

Many believe that "big data" will transform business, government, and other aspects of the economy. Liran Einav in his article he discuss how new data may impact economic policy and economic research. [2] Large- scale administrative data sets and proprietary private sector data can greatly improve the way we measure, track, and describe economic activity. They can also enable novel research designs that allow researchers to trace the consequences of different events or policies. We outline some of the challenges in accessing and making use of these data. We also consider whether the big data predictive modeling tools that have emerged in statistics and computer science may prove useful in economics.

Big Data are becoming a new technology focus both in science and in industry. This paper discusses the challenges that are imposed by Big Data on the modern and future Scientific Data Infrastructure (SDI).[3] The paper discusses a nature and definition of Big Data that include such features as Volume, Velocity, Variety, Value and Veracity.

Jia Deng et.al [7] and Ritendra Datta [8] et.al also proposed a method for image retrieval from huge data. The paper refers to different scientific communities to define requirements on data management, access control and security. The paper introduces the Scientific Data Lifecycle Management (SDLM) model that includes all the major stages and reflects specifics in data management in modern e-Science. The paper proposes the SDI generic architecture model that provides a basis for building interoperable data or project centric SDI using modern technologies and best practices. The paper explains how the proposed models SDLM and SDI can be naturally implemented using modern cloud based infrastructure services provisioning model and suggests the major infrastructure components for Big Data Infrastructure.

 On-command Digital universe with data prolife ring by institutions, Individuals and Machines at a very high rates. This data is categories as "Big Data"[4] due to its sheer Volume, Variety, Velocity and Veracity. Most of this data is unstructured, quasi structured or semi structured and it is heterogeneous in nature. The volume and the heterogeneity of data with the speed it is generated, makes it difficult for the present computing infrastructure to manage Big Data. Traditional data management, warehousing and analysis systems fall short of tools to analyze this data. Due to its specific nature of Big Data, it is stored in distributed file system architectures. Hadoop and HDFS by Apache is widely used for storing and managing Big Data. Analyzing Big Data is a challenging task as it involves large distributed file systems which should be fault tolerant, flexible and scalable. Map Reduce is widely been used for the efficient analysis of Big Data. Traditional DBMS techniques like Joins and Indexing and other techniques like graph search is used for classification and clustering of Big Data. [4] These techniques are being adopted to be used in Map Reduce. In this research paper the authors suggest various methods for catering to the problems in hand through Map Reduce framework over Hadoop Distributed File System.

The need for sound ecological science has escalated alongside the rise of the information age and "big data" across all sectors of society.[5] Big data generally refer to massive volumes of data not readily handled by the usual data tools and practices and present unprecedented opportunities for advancing science and informing resource management through data-intensive approaches.

The era of big data need not be propelled only by "big science" – the term used to describe large-scale efforts that have had mixed success in the individual-driven culture of ecology. Collectively, ecologists already have big data to bolster the scientific effort – a large volume of distributed, high-value information – but many simply fail to contribute. We encourage ecologists to join the larger scientific community in global initiatives to address major scientific and societal problems by bringing their distributed data to the table and harnessing its collective power.

III. PROPOSED SYSTEM

Figure 1 shows the block diagram of proposed architecture. The methodology consists of two major phases. One is the training phase and the other is the testing phase. Training phase consists of reading the data, pre-processing, extraction of useful features and train the feature vector. The first step is reading and pre-processing of data from the

database consists of data that are to be trained. Pre-processing is the step that makes data to accessible form. This step includes resizing, rearranging, etc. After the data is pre-processed we extract the useful and unique features that help for differentiating the data. Using CB-support vector machine these feature vectors are trained. Trained data will be stored in a knowledge base.

Testing phase is the evaluation phase. Here input data is given for test. Input data involved for pre-processing and feature extraction. After feature vector is extracted from the test data the feature vector is recognized using ANN classifier by using trained knowledge. Finally the test data is categorized based on the classification result.

A. Preprocessing

Input image is applied with image pre-processing steps to enhance the visual appearance of images. Color conversion to gray image and resizing is applied. Pre-processing is followed by feature extraction.

B. Gabor Feature

The Gabor filter is generally utilized as a part of the image features. The Gabor filter wavelet is the type of sine wave adjusted by the Gaussian coefficient. The Gabor filter is helpful for extracting local and global data. The Gabor filters are tunable band pass channel, multistage and multi resolution filter.

The Gabor filter eq. (1) is utilized as a part of texture segmentation, image representation. It offers ideal resolution in space and time domain. It gives better visual representation in the involved composition pictures. Be that as it may, the current Gabor parameter requires additional time utilization for feature extraction. The Gabor filter works on the frequency, orientation and Gaussian kernel.

$$Gabor(x, y, \theta, \varphi) = X \cdot Y \qquad (1)$$

$$X = \exp(-(x^2 + y^2) \div \sigma^2) \qquad (2)$$

$$Y = \exp(2\pi\theta(x\cos\theta + y\sin\theta)) \qquad (3)$$

The terms x and y (eq. 2 and eq. 3) is the position of the filter relative to the input signal [5]. The angular representation of the filter is represented as 'θ'. The angular orientation of the filter is represented as '$\emptyset$'.

C. ANN Classifier

This paper presents a new approach for scalable and reliable ANN classification. A neural network, more precisely referred to as Artificial Neural Network (ANN), is a quite difficult data analysis technique. It is based on a well-defined architecture of many interconnected artificial neurons. But it also takes advantage of distinct learning algorithms that efficiently learn from data utilizing this particular human inspired architecture. It is inspired by the human and named 'artificial' neuron because it is a simplified electronic version of a real human biological nerve cell called neuron. The human brain learns by changing the strength of the connection between neurons due to repeated stimulation by the same impulses. We refer to this strength with the term 'weight' of the connection links between different neurons. The artificial neuron is thus modeled in detail as the following so-called perception model.

In more practical terms neural networks are non-linear statistical data modeling tools. They can be used to model difficult relationships between inputs and outputs or to find patterns in data. Using neural networks as a tool, data warehousing firms are harvesting data from datasets in the process called as data mining. The difference between these data warehouses and ordinary databases is that there is actual manipulation and cross-fertilization of the data helping users makes more informed decisions.

Neural networks basically comprise three pieces: the architecture or model; the learning algorithm; and the activation functions. Neural networks are programmed or "trained" to ". . ." store, recognize, and associatively retrieve patterns or database entries; to solve combinatorial optimization problems; to filter noise from measurement data; to control ill-defined problems; in summary, to estimate sampled functions when we do not know the form of the functions." It is accurately these two abilities (pattern recognition and function estimation) which make artificial neural networks (ANN) so prevalent a utility in data mining. As data sets grow to massive sizes, the need for automated processing becomes clear. With their "model-free" estimators and their dual nature, neural networks serve data mining in a myriad of ways.

The ANN classification most common action in data mining is classification. It recognizes patterns that describe the group to which an item belongs. It does this by examining existing items that already have been classified and inferring a set of rules.

IV. RESULTS AND DISCUSSION

Below Figure 2 shows the input image of testing phase. Input image is applied with pre-processing steps like color conversion as show in Figure 3.

Figure 2: Input color image

Image preprocessing is followed by feature extraction, in our proposed system Gabor features of the image is extracted and trained using ANN method.

Gray Image

Figure 3: Color Converted Input Image

Using ANN classifier image is retrieved, which is shown in the Figure 4.

Figure 4: Retrieved Images

V. CONCLUSION

The proposed system presents an integration of scalable clustering method with machine learning classifier. The system effectively presents an efficient output for large set of database. The primitive ANN is not feasible for huge data set due to complexity in volume. ANN gives out the best boundary for large data set. A micro clustering of ANN scan the entire data set only once and presents an high micro-clusters that carry the statistical summaries of the data such that the summaries maximize the benefit of learning the ANN.
